NEA Scout Overview

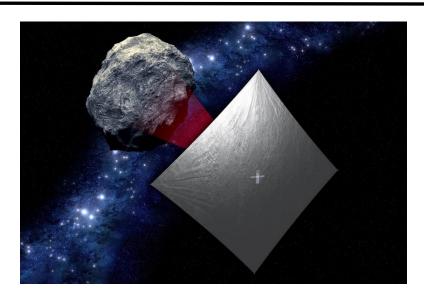

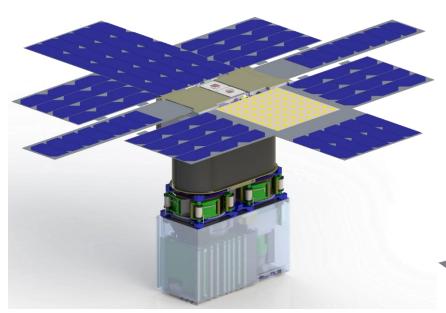

Goal:

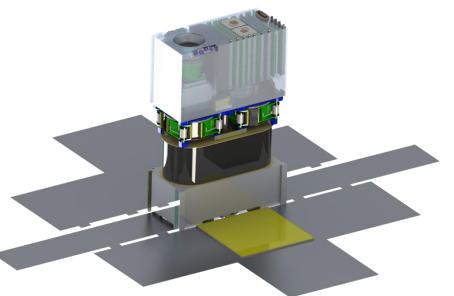

Characterize a NEA during flyby while demonstrating low cost reconnaissance capability

Vehicle and Mission Details:

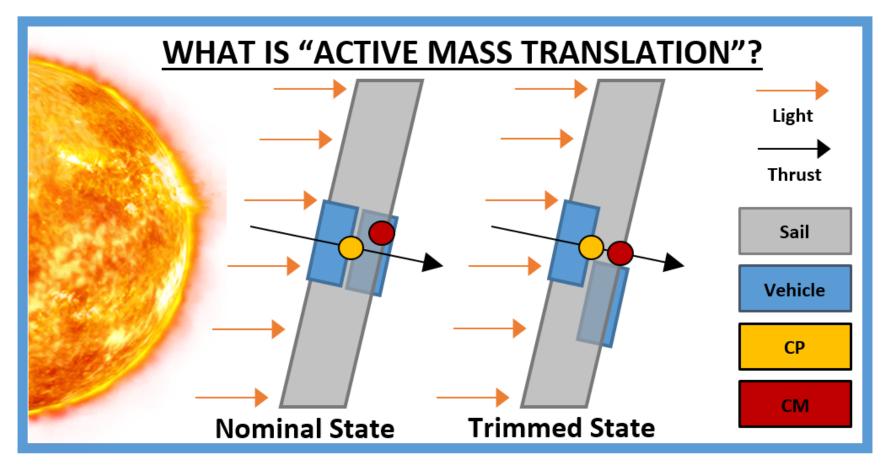

- 6U CubeSat manifested on SLS Exploration Mission 1
- 86m² solar sail propulsion
- 2.5 year mission
- 1.5 x10^8 km (1 AU) distance from Earth

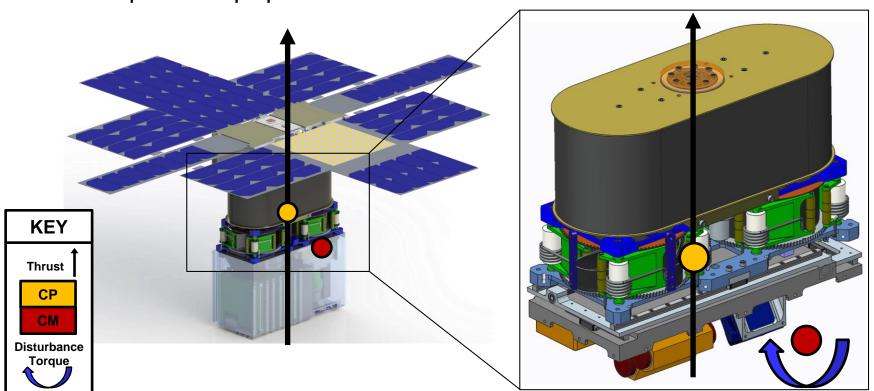

The AMT will move one portion of the NEA Scout relative to the other. This translation of mass will alter the inertial properties of the vehicle and align the CP and CM

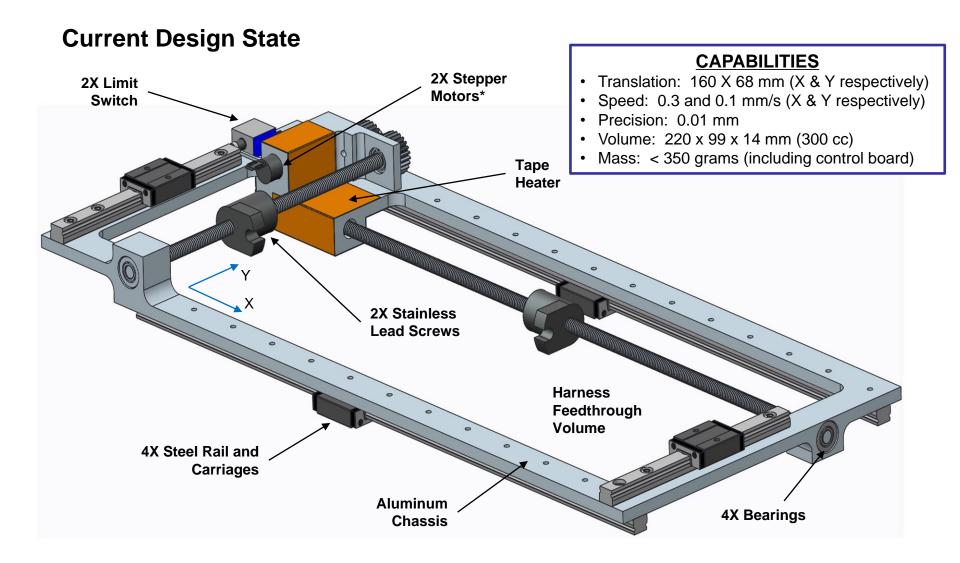

Problems and Challenges

- NEA Scout's center of mass (CM) and center of pressure (CP) are not collinear with the estimated thrust vector. This creates a disturbance torque. Furthermore, the CP is fore of the CM, creating a naturally unstable vehicle and necessitating an active control mechanism.
- Little mass and volume available. This challenge is compounded by the vehicle's total mass (14 kg) and volume (6 Liters) requirement. The AMT was originally given 250 grams and a volume of 226 x 105 x 17 mm (400 cc). This volume and mass will include: an X-Y translation stage, thermal controls, limit switches, and a wire harness. The wire harness must pass through the AMT and survive exposure to deeps space environments.

 $^{^{\}star}$ Stepper Motors are housed inside of the aluminum block and are not readily visible

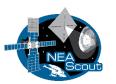

Nominal State

Takeaways

Innovations

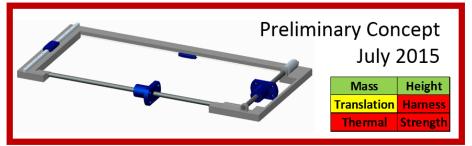

- Unique use of flight system inertial augmentation as trimming mechanism
- Translation Table tailored for deep space CubeSat environments and mechanical demands
- "Inverted" design allows for wire harness to pass through translation stage

Lessons Learned

- Treat CubeSats as they are: lower cost, higher risk projects
- · Test as early as possible
- Complete rough thermal and loads analysis between concept and revising phases
- Use additive manufacturing to increase design progress during prototype phase

♦ Forward Work

- Wire Bundle design, safety, and routing
- Development Unit Testing (life cycle, thermal vacuum, random vibration)
- Higher fidelity thermal and stress analysis
- Design simplification and mass reduction

Development of a High Performance, Low Profile Translation Table with Wire Feedthrough for a Deep Space CubeSat

Alex Few NASA Marshall Space Flight Center

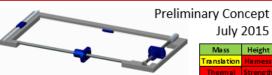

PROBLEM STATEMENT:

Near Earth Asteroid (NEA) Scout, a 6U cubesat, will use an 86 m² solar sail to travel about 1 astronomical unit (1.5 x 10⁸ km) to a near-earth asteroid for observation and reconnaissance. Nine months ago, the project introduced a new subsystem called the Active Mass Translator (AMT). The AMT will be designed to overcome a controllability challenge created by a misalignment of the sail's center of pressure (CP) and the vehicle's center of mass (CM). Furthermore, the CP is fore of the CM, creating a naturally unstable vehicle and necessitating an active control mechanism.

CHALLENGES:

As with any subsystem introduced late in the design process, there is little mass and volume available. This challenge is compounded by the vehicle's total mass (14 kg) and volume (6 Liters) requirement. The AMT was originally given 250 grams and a volume of 226 x 105 x 17 mm (400 cc). This volume and mass will include: an X-Y translation stage, thermal controls, limit switches, and a wire harness. The AMT will reside near the geometric center of the vehicle, splitting the avionics and reaction control systems. The wire harness must pass through the AMT and survive exposure to deeps space environments.

LESSONS LEARNED

- Treat CubeSats as they are: lower cost, higher risk projects
- Test as early as possible
- Complete rough thermal and loads phases
- Use additive manufacturing to increase design progress during prototype phase

CAPABILITIES

- Translation: 160 X 68 mm (X & Y respectively)
- Speed: 0.3 and 0.1 mm/s (X & Y respectively)
- Precision: 0.01 mm
- Volume: 220 x 99 x 14 mm (300 cc)
- Mass: < 350 grams (including control board)
